1 Introduction

Recent publications reveal that high frequency trading (HFT) is responsible for 10 to 70 per cent of the order volume in stock and derivatives trading (Gomber et

al. 2011; Hendershott and Riordan 2011; Zhang 2010). This observation leads to a controversial debate over positive and negative implications of HFT for the liquidity and efficiency of electronic securities markets and over the costs and benefits of and needs for market regulation. Currently the European Union (EU) is considering the introduction of a financial transaction tax to curtail the harmful effects of HFT strategies. The consideration behind this market policy is based on the assumption that the very short-term oriented HFT trading strategies lead to market frictions. This current discourse shows that the arguing parties do not homogeneously define HFT. Reasons for this are the proponents' different but intertwined perspectives, which lead to new unanswered questions in numerous subjects of expertise. From a macroeconomic point of view the question arises if HFT constrains or supports the allocation function of financial markets. Capital market research and information management research raise questions about the future form of intermediation in securities trading and the coming architecture of markets, about the HFT's impact on liquidity and about price volatility. Financial authorities and regulators discuss whether HFT has a stabilizing or destabilizing function on financial systems and how a future regulation should be shaped.

This collection of articles shall help to develop a common definition of HFT and contribute to the ongoing discussions. To that end we have collected articles from representatives of information systems, business management, the Deutsche Bundesbank and the Deutsche Boerse AG. The following scientists and practitioners participated in the discussion (in alphabetical order):

- Prof. Dr. Hans-Peter Burghoff and Arne Breuer, Chair of Business Economics, especially Banking and Financial Services, University of Hohenheim, Germany.
- Prof. Dr. Peter Gomber, Chair of Business Economics, especially e-Finance,

Johann Wolfgang Goethe-University of Frankfurt, Germany.

- Dr. Joachim Nagel, Member of the Board of Directors, and Dr. Rafael Zajonz, Central Market Analysis, Portfolio, Deutsche Bundesbank, Frankfurt, Germany.
- Rainer Riess, Managing Director of the Frankfurter Wertpapierbörse (FWB), and Michael Krogmann, Executive Vice President of Xetra Market Development of Deutsche Börse AG, Frankfurt, Germany.
- Prof. Dr. Ryan Riordan, Institute for Information Systems and Management, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany.

HFT is a part of algorithmic trading. Gomolka (2011) defines algorithmic trading as the processing and/or execution of trading strategies by the means of intelligent electronic solution routines (known as algorithms). Thus algorithmic trading encompasses computer-supported trading as well as computer-generated sell-side and buy-side market transactions. Algorithmic trading strategies can be both short-term and long-term oriented.

In general, HFT is defined as real-time computer-generated decision making in financial trading, without human interference and based on automatized order generation and order management. HFT encompasses short-term trading strategies, which – in extreme cases – operate in the range of microseconds using minimal price differences. HFT thus results in minimal profit margins per transactions and exhibits very short holding periods of securities positions.

However, HFT definitions vary and various properties of HFT are not consistently discussed in the literature. Aldridge's (2009) definition of HFT holding periods range from milliseconds to one day. Durbini (2010) on the other hand describes HFT as trading strategies, which covers seconds or milliseconds only. According to Brogaard (2010), HFT is extremely short-term buying or selling with the intention to profit from minimal price fluctuations.

125 Further characteristics are often men- 127
126 tioned but are not always included in 128
127 HFT definitions, such as the exclusive use- 129
128 age by professional/institutional investors 130
129 in proprietary trading, real-time data 131
130 processing and direct market access (Da- 132
131 corogna et al. 2001). Another controver- 133
132 sial issue is the avoidance of overnight 134
133 risk (Aldridge 2009). Other definitions 135
134 underline the role of HFT as financial 136
135 intermediary (Hendershott and Riordan 137
136 2011) or try to find differences among 138
137 the implemented trading strategies (Ye 139
138 2011).

139 On the basis of the broad HFT defini- 140
140 tion given before the authors in this arti- 141
141 cle will shed light on the following ques- 142
142 tions: (1) How does HFT influence the 143
143 liquidity and efficiency of electronic secu- 144
144 rities markets? (2) What are the costs and 145
145 benefits of, and what are the needs for a 146
146 HFT regulation?

147 Peter Gomber analyzes HFT from a 148
148 market microstructure perspective, and 149
149 finds HFT to be a central element of the 150
150 value creation chain in securities trad- 151
151 ing. As part of the value creation chain, 152
152 HFT contributes to increased efficiency 153
153 and reduced explicit and implicit transac- 154
154 tion costs. In his eyes, regulation of HFT 155
155 could lead to dramatic changes in market 156
156 behavior, while an inappropriate regula- 157
157 tion might even be counterproductive for 158
158 market quality. Gomber sees the prob- 159
159 lems for profound research on HFT in the 160
160 lack of data available for empirical stud- 161
161 ies. Again this leads to adverse effects in 162
162 discussions of the topic in the public, in 163
163 the media, and with regulators.

164 Ryan Riordan also looks at HFT from 165
165 the perspective of market microstructure 166
166 and interprets HFT as one form of tech- 167
167 nological financial intermediation which 168
168 contributes to the efficiency of opera- 169
169 tions in exchange trading. In his eyes, 170
170 HFT plays an important role in the pro- 171
171 cess of price formation and influences the 172
172 size of transaction costs in securities trad- 173
173 ing. According to him, one cannot yet 174
174 say whether HFT will have a positive or 175
175 a negative impact on the capital markets. 176
176 However, he sees major advantages in a 177
177 highly technologized market. It is no al- 178
178 ternative for him to turn back the wheels 179
179 and return to a backward oriented, arti- 180
180 ficially slowed, regulated trading, which 181
181 is based on human intermediation.

182 Rainer Riess and Michael Krogmann 183
183 describe HFT as the highest evolution- 184
184 ary level of securities trading. In their 185
185 opinion HFT leads to faster processing 186

of information, to an increase in liq- 187
188 uidity, and thus added values for the 189
189 overall economy. The authors describe 190
190 how HFT is currently technically real- 191
191 ized and integrated into trading opera- 192
192 tions at the exchange, and deduct their 193
193 arguments accordingly. From the point of 194
194 view of Deutsche Börse, HFT is mainly 195
195 used by institutional investors in pro- 196
196 prietary trading and focuses on highly 197
197 liquid stocks. The authors correlate the 198
198 rise of HFT with a continuous improve- 199
199 ment of the electronic trading system XE- 200
200 TRA, which – from the point of view 201
201 of Deutsche Börse – benefits all market 202
202 participants in the same way. In the eyes 203
203 of Riess and Krogmann, a future regula- 204
204 tion of HFT should primarily focus on 205
205 equal chances of competition in the EU- 206
206 area, in order to create “a level playing 207
207 field“. From the point of view of Deutsche 208
208 Börse, it is necessary not only to imple- 209
209 ment security mechanisms on the side of 210
210 exchanges but also with HFT-firms.

211 Arne Breuer and Hans-Peter Burghof 212
212 also recognize that, due to HFT, infor- 213
213 mation can be processed more perfectly 214
214 and faster than ever before. They look at 215
215 the topic from the perspective of finan- 216
216 cial economics. This point of view leads 217
217 them to believe that more and faster in- 218
218 formation does not necessarily lead to 219
219 a correct determination of the intrin- 220
220 sic value of financial instruments. Rather 221
221 HFT processes short-term information, 222
222 which primarily is made of short-term 223
223 volume and short-term time series data, 224
224 and thus does not contribute to the eval- 225
225 uation of the intrinsic values. The au- 226
226 thors vote for a stricter regulation of HFT. 227
227 However, before this can be done, more 228
228 analyses should be conducted. For this, 229
229 more data are necessary.

230 Finally, Joachim Nagel und Rafael Za- 231
231 jonz argue from the perspective of reg- 232
232 ulators. A blanket judgment on HFT is 233
233 from the regulators’ point of view nei- 234
234 ther adequate nor would it lead to im- 235
235 provements of the regulatory framework 236
236 regarding transparency, stability, and ef- 237
237 ficiency. The impact of HFT on the effi- 238
238 ciency of securities trading is – due to the 239
239 absence of a scientific discussion – still 240
240 unclear for the regulators. The possibility 241
241 to destabilize the market due to HFT in 242
242 volatile market situations is regarded as 243
243 critical but should be looked into in de- 244
244 tail. From the point of view of the authors 245
245 “market friendly” strategies exist, a fact 246
246 which can be judged positively. But there 247
247 are also “unfriendly strategies“, which – 248

from their perspective – can be catego- 187
188 rized as potentially harmful. In the cen- 189
189 ter of their article, the authors formu- 190
190 late the wish that this complex topic may 191
191 be discussed more intensely by the sci- 192
192 entific community in the future, in order 193
193 to better understand which fundamental, 194
194 regulatory measures should be applied to 195
195 HFT.

2 High Frequency Trading Regulation Required at a Reasonable Level

220 It is uncommon for a specific subject 221
221 in the field of securities trading and IT- 222
222 innovation to draw as much public atten- 223
223 tion as high frequency trading (HFT) has 224
224 been doing in recent months. Merely a 225
225 special field for a small group of experts 226
226 prior to 2010, it is now a frequent part 227
227 of the general news coverage. Against the 228
228 background of the recent debt crisis, the 229
229 current volatility and market turmoil as 230
230 well as the “US Flash Crash” on May 6, 231
231 2010 lead to this extreme attention. Sev- 232
232 eral parties attempt to exert pressure on 233
233 politics and regulation by making HFT 234
234 responsible for that crisis and the high 235
235 market volatility. In reaction to the afore- 236
236 mentioned incidents and to the subse- 237
237 quent public discussions, the regulatory 238
238 authorities of international financial cen- 239
239 ters have debated the adoption of vari- 240
240 ous regulatory measures and now pro- 241
241 pose regulatory procedures, which cur- 242
242 rently substantiate especially in Europe 243
243 and will presumably be approved in 2012 244
244 in the context of the revision of the Mar- 245
245 kets in Financial Instruments Directive 246
246 (MiFID).

247 Basically, the trading strategies based 247
248 on HFT can be subdivided into active 248

249 and passive ones. Whereas passive strate- 311
250 gies provide other market participants 312
251 with trading opportunities in terms of 313
252 quotes and limit orders (e.g. electronic 314
253 market making), active strategies primar- 315
254 ily attempt to exploit imbalances of as- 316
255 set prices in fragmented markets (e.g. 317
256 primary market and multilateral trad- 318
257 ing facilities), discrepancies in valua- 319
258 tion between different asset classes (e.g. 320
259 between derivatives and their underly- 321
260 ings) or deviances of current asset val- 322
261 uations compared to historical correla- 323
262 tions (e.g. in the so-called pairs trading) 324
263 immediately after the emergence of these 325
264 trading/arbitrage opportunities. 326

265 The emerging academic literature, 327
266 which analyzes the effects of HFT based 328
267 strategies on market quality, shows 329
268 mostly positive impact (for a system- 330
269 atic outline of academic research con- 331
270 cerning HFT see Gomber et al. 2011). 332
271 Regarding price discovery, liquidity and 333
272 volatility, most studies discover positive 334
273 effects of HFT. Only a few publications 335
274 indicate that HFT can increase the ad- 336
275 verse selection problem under specific 337
276 circumstances, and in the case of the “US 338
277 Flash Crash” another survey (Kirilenko 339
278 et al. 2011) reveals that HFT can increase 340
279 volatility. 341

280 The growing market efficiency and a 342
281 reduction of explicit and implicit trans- 343
282 action costs triggered by HFT is an ob- 344
283 vious issue particularly for those mar- 345
284 ket participants who used to capitalize on 346
285 intermediary services and broad bid/ask 347
286 spreads in a formerly less efficient and 348
287 less liquid trading environment. In con- 349
288 trast to off-exchange trading via inter- 350
289 nalization and so-called dark pools, i.e. 351
290 non-transparent execution venues, HFT 352
291 market-making strategies on lit markets 353
292 face relevant adverse selection costs as 354
293 they provide liquidity on the market 355
294 without knowing their counterparties. 356
295 Within their internalization systems and 357
296 dark pools in the OTC field, banks and 358
297 brokers are aware of their counterparties’ 359
298 identities and can benefit from this infor- 360
299 mation. Contrary to this, HFTs in lit mar- 361
300 kets are not aware of the toxicity of their 362
301 counterparts and are – analogous to mar- 363
302 ket makers – exposed to the problem of 364
303 adverse selection. 365

304 Inappropriate regulation of HFT based 366
305 strategies or an impact on HFT business 367
306 models due to excessive burdens might 368
307 turn out to be counterproductive and 369
308 lead to unforeseeable consequences for 370
309 the quality of markets. However, abusive 371
310 strategies have to be combated effectively 372

by the regulators. Particularly the analy-
sis of the “US Flash Crash” with its dis-
cussed solution approaches can hardly
be transferred to the European situation,
since the issues related to the “US Flash
Crash” primarily result from the US mar-
ket structure. In Europe, where a more
flexible best execution regime is imple-
mented and a share-by-share volatility
safeguard regime has been in place for
two decades, no market quality problems
related to HFT have been documented so
far. Therefore, a European approach to
the subject matter is required, and Eu-
rope should be cautious about address-
ing and fixing a problem that exists in a
different market structure and thus creat-
ing risks for market efficiency and market
quality.

Any regulatory interventions in Europe
should try to preserve the benefits of HFT
while mitigating the risks as far as pos-
sible by assuring that (i) HFT firms are
able to provide documentation on their
algorithms upon authorities’ request and
to conduct back-testing, (ii) markets are
capable of handling peaks in trading ac-
tivity and apply safeguards to react to
technical issues of their members’ algo-
rithms, (iii) a diversity of trading strate-
gies prevails to prevent systemic risks,
(iv) co-location and proximity services
are implemented on a level playing field,
(v) regulators have a complete overview
of the possible systemic risks which could
be triggered by HFT, and have employ-
ees who have the knowledge and the tools
to assess the impact of the trading algo-
rithms on market quality and the asso-
ciated risks. Furthermore, it is crucial
that market places in a fragmented envi-
ronment develop coordinated safeguards
and circuit breakers, which mirror the
HFT reality and enable all market partic-
ipants to react adequately even in market
stress.

Regulatory proposals demanding con-
tinuous liquidity provision by HFT in the
sense of market marking obligations or
minimum quote lifetimes miss the mark
and are not suitable to improve market
stability or market integrity. They rather
contribute to a decrease in market quality
and higher transaction costs.

At first sight, demanding obligations
for HFTs to provide quotes seems an ap-
propriate measure to tackle the problem
of a sudden liquidity withdrawal. How-
ever, it is highly doubtful whether any
rule can force market makers to buy in
the face of overwhelming selling pres-
sure. In such a situation they might rather

take the risk of being fined for not fulfill-
ing their obligations. Many HFT strate-
gies are characterized by rapid closing
of built-up positions to minimize risk.
Hence, an obligation to provide liquidity
and thereby risk capital is in sharp con-
trast to many HFT business models. Due
to the significant regulatory costs those
obligations would potentially lead to a
retreat from the market and thus to a
notable loss of liquidity.

Also a minimum order lifetime, which
at first glance appears to be useful to
avoid fast order submissions and imme-
diate cancellations, would lead to a signif-
icant change in market behavior. Market
participants are then no longer able to
react quickly and adequately to market-
exogenous information (e.g. ad-hoc
news) and the necessity to keep an order
in the order book presents a free option
for other market participants. Besides,
the existence of minimum order lifetimes
would lead to an implementation of trad-
ing strategies capitalizing on the “lock in”
of orders. HFT would anticipate the ac-
companied risks and costs and attempt
to compensate these costs with higher
spreads, which again would have negative
effects on market quality. In this debate it
should not be neglected that speed is the
key tool for HFTs’ risk management.

HFT is an important factor in mar-
kets that are driven by sophisticated tech-
nology on all layers of the trading value
chain. However, discussions on this topic
often lack sufficient and precise informa-
tion. A remarkable gap between the re-
sults of academic research on HFT and
its perceived impact on markets in public,
media and regulatory discussions (Euro-
pean Commission 2010) can be observed.
Here, the provision of granular and reli-
able data by the industry can assist em-
pirical research at the interface of finance
and IS to provide important contribu-
tions to a reasonable regulation of HFT.
This regulation should eventually mini-
mize the inherent risks of the technol-
ogy in question without hindering the
indisputably existing positive effects for
market quality.

Prof. Dr. Peter Gomber
University of Frankfurt
E-Finance Lab

3 High Frequency Trading (HFT) – A New Intermediary

Financial markets require intermediaries
to provide liquidity and immediacy for

373 other participants. These intermediaries, 435
374 often called market makers or special- 436
375 ists, were often afforded special status 437
376 and located on the trading floor, or close 438
377 to the trading mechanism of exchanges. 439
378 The automation of financial markets has 440
379 increased their trading capacity and in- 441
380 termediaries have expanded their use of 442
381 technology. This has resulted in a reduced 443
382 role for traditional human market mak- 444
383 ers and led to the rise of a new intermedi- 445
384 ary, referred to as high frequency traders 446
385 (HFTs).

386 This development has been made possi- 447
387 ble by the technological innovations in 448
388 recent years. HFT strategies usually make 449
389 use of the high speed technologies to 450
390 build up and unwind positions within 451
391 milli- and microseconds. Prerequisites 452
392 for this development were the reduction 453
393 of system latency and the increase 454
394 of computing power and data process- 455
395 ing capabilities of computers. Next to the 456
396 large investments in HFT, exchanges have 457
397 also invested large amounts of money in 458
398 their IT infrastructure. For example, the 459
399 costs of a high-speed connection between 460
400 Chicago and New York are estimated 461
401 around \$200,000 per mile (Forbes 2010). 462
402 The question remains whether these in- 463
403 vestments are justified with regard to the 464
404 increase of overall market quality and 465
405 welfare that results from higher HFT 466
406 activity on the market.

407 Like traditional intermediaries HFTs 467
408 hold little inventory, have short hold- 468
409 ing periods, and trade often. Unlike tra- 469
410 ditional intermediaries, however, HFTs 470
411 are not granted preferential access to the 471
412 market not available to others and they 472
413 employ advanced and innovative tech- 473
414 nology to intermediate trading. With- 474
415 out such privileges, there is no clear ba- 475
416 sis for imposing the traditional obliga- 476
417 tions of market makers on HFT. The sub- 477
418 stantial, largely negative media coverage 478
419 of HFT and the so called “flash crash” 479
420 on May 6, 2010 raise significant interest 480
421 and concerns about the role HFT play in 481
422 the stability and price efficiency of finan- 482
423 cial markets. The predominantly negative 483
424 coverage seems mostly unfounded. 484

425 Overall, HFTs’ impact is similar to 485
426 that of other intermediaries and specu- 486
427 lators. Speculators can improve price ef- 487
428 ficiency by obtaining more information 488
429 on prices and by trading against pric- 489
430 ing errors. Manipulative strategies and 490
431 predatory trading could decrease price 491
432 efficiency. Reducing pricing errors im- 492
433 proves the efficiency of prices. HFTs’ in- 493
434 formational advantage, which is driven 494

by the technology they employ, is short- 435
term. It is unclear whether or not this 436
short-term information and intraday re- 437
ductions of pricing errors facilitate better 438
financial decisions and resource alloca- 439
tions by firms and investors. If the short- 440
term information – that HFTs price in – 441
would not otherwise become public mi- 442
croseconds later, HFT clearly plays an im- 443
portant role (Hendershott and Riordan 444
2011). It would be an important positive 445
role of smaller pricing errors if these cor- 446
responded to lower implicit transaction 447
costs by long-term investors. 448

One important point left unaddressed 449
thus far is whether or not HFTs engage in 450
manipulative or predatory trading. Their 451
use of technology may allow HFTs to ma- 452
nipulate prices at speeds that are unde- 453
tectable by slower traders. A manipula- 454
tive strategy might be the ignition of a 455
price movement in one direction only in 456
order to trade on the opposite side of the 457
market as proposed by the SEC (2010) 458
and therefore cause significant pricing 459
errors. As is frequently done, one can 460
argue whether the underlying problem 461
of possible manipulation lies with the 462
manipulator or the market participant 463
who is manipulated. In the SEC exam- 464
ple, the passive manipulation could not 465
succeed if there were no price matching. 466
The manipulation stories could be tested 467
with more detailed data identifying each 468
market participant’s orders, trading, and 469
positions in all markets. 470

Despite the strong evidence of the posi- 471
tive role of HFT for the efficiency of 472
price determination and trading costs 473
(Hendershott et al. 2011; Brogaard 2010; 474
Zhang and Riordan 2011), regulators and 475
the media are certain that they must be 476
regulated. It is, however, unclear and also 477
debatable how we should regulate HFT. 478
Assuming that some, or most, of their 479
activities contribute positively to liquid- 480
ity and price efficiency, which parts of 481
their trading should we regulate? There 482
are controversially discussed suggestions 483
to restrict HFTs’ mostly passive trading or 484
to enforce a minimum order life on limit 485
orders. Restricting HFTs’ ability to trade 486
actively necessarily impedes their ability 487
to manage the risks associated with in- 488
termediation. This may lead to less in- 489
termediation and lower liquidity. Impos- 490
ing minimum order lives on limit orders 491
may also negatively impact HFTs’ 492
ability to manage trading risks during 493
volatile market periods that existed be- 494
fore HFT dominated the equity market. 495

Finally, the discussions of US and Euro- 435
pean regulation should take into account 436
specific differences of both markets. De- 437
spite the high market fragmentation, the 438
European market has maintained a com- 439
parably high degree of efficiency. This is 440
also due to the help of HFTs. They make 441
use of arbitrage strategies to dissolve ex- 442
isting price deviations within seconds 443
which results in an interconnectedness of 444
European markets. 445

A final point is a more general one 446
on technology investments. HFTs must 447
make a large and long-term investment in 448
technology, both hardware and software. 449
This investment in technology seems to 450
have to paid-off both for HFTs and the 451
equity markets. If regulation were to 452
negatively impact the returns on invest- 453
ments in HFT technologies by reducing 454
the profitability of intermediation, fewer 455
firms will be willing to invest in these 456
technologies. This may lead to a situ- 457
ation in which one or two highly special- 458
ized firms dominate intermediation, 459
which ultimately leads to less competi- 460
tion, lower liquidity and reduced price- 461
efficiency. Competition, ease of market 462
entry and the use of specialized and in- 463
novative technology seem to be the best 464
guarantors of market stability. 465

It is hard to imagine a situation in 466
which HFTs are able to artificially ma- 467
nipulate prices for longer periods of 468
time given the intense competition other 469
HFTs. HFTs are one type of intermediary. 470
When thinking about the role HFT plays 471
in markets it is natural to try to compare 472
the new market structure to the previ- 473
ous market structure. Some primary dif- 474
ferences are that there is free entry into 475
HFT, HFTs do not have a designated role 476
with special privileges, and HFTs do not 477
have special obligations. When consider- 478
ing the optimal industrial organization of 479
the intermediation sector, which includes 480
regulation, market structure, technology 481
and incumbency, HFT more closely re- 482
sembles a highly competitive environ- 483
ment than traditional market structures. 484
A central question is whether there were 485
benefits of the more highly regulated and 486
less technology intensive intermediation 487
sector which outweigh the costs of lower 488
innovation and higher entry costs typi- 489
cally associated with regulation. The an- 490
swer to this question seems thus far to be 491
a resounding “no”. 492

4 High Frequency Trading – An Exchange Operator’s Perspective

4.1 High Frequency Trading – Myth and Reality

On 2010-09-30, the U.S. Securities and Exchange Commission (SEC) and the Commodity Futures Trading Commission (CFTC) (2010) issued a joint report showing that the so-called “flash crash”, a sequence of events which made prices plunge throughout the US stock market, was caused by an incorrectly programmed trading algorithm of a traditional investment company which did not use high frequency trading (HFT). Nevertheless, HFT has gained massive public attention ever since. The news media, as well scientists and regulatory authorities, are busy discussing and analyzing the effect of HFT on the global capital markets. While the public perception of HFT is largely critical – and driven by headlines demanding a HFT ban or, at least, strict regulation – scientific analysis comes to rather different conclusions (see Gomber’s discussion above). According to Brogaard’s (2010) study of HFT, blaming HFT for the US flash crash is not the only popular fallacy regarding the role of HFT in securities trading. Brogaard’s analysis of NASDAQ data showed that for 65% of the time HFT accounted for the best bid and ask quotes. Also, Brogaard found no evidence suggesting that HFT firms systematically engage in market abuse, e.g. by illegally taking advantage of information about client orders, the so-called “front running”. Since HFT firms are proprietary traders, they do not have any clients. Generally, scientific analysis did not find a correlation between HFT and market abuse. The Netherlands Authority for the Financial Markets (AFM 2010) considers HFT as a legitimate trading method which is not market abusive under normal circumstances. According to Gomber, academic papers mostly could not find evidence for negative effects of HFT on market quality. Moreover, the Germany-based Karlsruhe Institute of Technology (KIT) concluded their study based on analysis of NASDAQ data with the finding that HFT even worked as a buffer against plunging stock prices during the crisis years 2008 and 2009 (Zhang and Riordan 2011).

4.2 Insights of an Exchange Operator

We live in a technology-driven society, continuously striving to further improve and advance the achievement potential of our economy as well as of nearly every aspect in our everyday life: can anyone imagine a commercial flight today without the aid of an autopilot, or modern microsurgery without robotics? These advancements are by no means ends in themselves but serve a greater good. Just the same goes for the ever increasing speed in securities trading – a development which leads to continuously improving general market quality and also to more efficient risk management for every market participant. The faster the market data transmission, the faster investors are able to adapt to ongoing market developments. This does not only have a very positive effect on the safety in securities trading but also on transaction cost: faster trading leads to tighter spreads and, therefore, to higher liquidity. The implicit transaction costs of every securities trade are determined mainly by liquidity and account for up to 80 percent of the overall transaction costs, while the explicit transaction costs – commissions, fees, taxes – are of minor significance. With this in mind, Deutsche Börse started long before the advent of HFT to improve the trading infrastructure of its electronic trading platform Xetra, especially in view of ever decreasing systemic latency. At the same time, Deutsche Börse further developed the security mechanisms and technologies respectively adapted them to the increasing demands of a more and more sophisticated and faster trading system, one of them being the very effective instrument of the volatility interruption, introduced in 1999. This security mechanism is used in extremely volatile market phases and leads to higher price stability: whenever an indicative price is outside the price range – which is pre-defined for every security traded on Xetra – a volatility interruption will be initiated around the reference price.

While continuously advancing the technical infrastructure, Deutsche Börse expanded its offer of individually selectable bandwidths for market participants connected to Xetra from 512 Kbit/sec up to 2 Mbit/sec for their Values API interfaces. In 2008, for Xetra members requiring even faster market data transmission and more order book depth, an additional interface with

a bandwidth of 1 Gbit/sec was implemented, called Enhanced Broadcast Solution respectively Enhanced Transaction Solution. Today, bandwidths of up to 10 GBit/sec are available. With the introduction of the so-called “non-persistent” orders in 2009, Deutsche Börse further enabled Xetra members to optimize their response times to price changes thanks to even faster data processing. “Non-persistent” orders are not saved in exchange systems and are thus designed not to be executed after volatility interruptions.

In late 2011 Deutsche Börse complemented its connectivity portfolio with the FIX (Financial Information Exchange) gateway. Market participants using this protocol now are able to connect to Xetra far more easily.

However, there was one latency factor left that even the most sophisticated technology could not overcome: the propagation delay due to physical distance. For every 100 km which a market participant’s trading engine and the trading system of Xetra are physically apart, transaction latency increases by 1 msec approximately. This could mean a true competitive disadvantage for market participants relying on ultra low latency. Deutsche Börse addressed this growing market demand by introducing its proximity services in 2006. By placing the trading engine of distant Xetra members not only virtually but physically close to the exchange back end – a process called co-location – the travel time of the market data could be drastically reduced. Today, 141 Xetra members take advantage of Deutsche Börse’s co-location offer.

Thanks to a continuously perfected trading infrastructure and the introduction of proximity services, Deutsche Börse has not only remained competitive on an international level but has also prepared Xetra optimally for the needs of HFT firms. Over the last few years, systemic latency on Xetra has been further reduced notwithstanding a dramatic increase of technical transactions – an advantage to all market participants alike: a fair, equal access to Xetra and the pre- and post-trade transparency characteristic of a regulated exchange make sure that every investor enjoys all advantages Deutsche Börse’s trading platform has to offer.

While being a minority, HFT firms nevertheless play an important role in improving the order book quality on Xetra, e.g. by bundling the very heterogeneous order flow. There are three orga-

621 nized forms of HFT on Xetra: the propri-
622 etary trading of investment firms, hedge
623 funds, and proprietary trading compa-
624 nies. Two types of trading prevail: first of
625 all, the so-called electronic liquidity pro-
626 vision. In this case, HFT firms act as vol-
627 untary market makers, adding liquidity
628 to a multitude of securities. The second
629 type of HFT on Xetra is called statistical
630 arbitrage which leads to improved price
631 discovery. Both types of HFT account
632 for tighter spreads and, ultimately, im-
633 proved market efficiency on Xetra. So far,
634 Deutsche Börse could find no evidence of
635 HFT having lead to destabilizing markets
636 during periods of market turmoil, e.g. by
637 strengthening trends. During the highly
638 volatile market phase in August 2011, the
639 trading volume on Xetra increased tem-
640 porarily to 107 Million transactions on
641 one single day. Despite up to 30 volatil-
642 ity interruptions, the average transaction
643 processing took only 0.4 msec longer
644 than usual. System availability was guar-
645 anteed at all times, Xetra members did
646 not have to face any restrictions, let alone
647 system failure. Deutsche Börse's market
648 security mechanisms made sure that all
649 trading activities could be executed prop-
650 erly and continuously while price stabil-
651 ity was guaranteed even during market
652 turmoil.

653 Thus, Deutsche Börse succeeded in adv-
654 vancing the Xetra infrastructure in terms
655 of continuously decreasing systemic lat-
656 ency and, at the same time, met the
657 permanently increasing needs regarding
658 safety and speed of its trading system
659 even before the term HFT came up.

661 4.3 Regulatory Recommendations

662
663 Within a national economy it is the ex-
664 plicit function of a securities exchange to
665 facilitate the most efficient employment
666 of capital, ensuring best possible corpo-
667 rate financing and re-financing. HFT, as
668 it is today, supports faster processing of
669 economically relevant data and leads to
670 higher liquidity in the trading of com-
671 pany shares. Thanks to a stable, high-
672 performance trading system, Deutsche
673 Börse was able to integrate HFT success-
674 fully and to use the positive effects of
675 HFT to improve overall market quality.
676 This would not have been possible with-
677 out Deutsche Börse's principle of equal
678 access and a fair set of rules applying to
679 every market participant trading on Xe-
680 tra alike. From a regulatory perspective
681 – and keeping MiFID's ultimate goal of
682 creating an EU-wide "level playing field"

in mind – comprehensive rules regard-
ing HFT definitely would make sense.
Therefore, Deutsche Börse supports all
measures to enhance transparency, e.g.
the complete registration of all market
participants and a full recording of all
their trading activities – traditional trad-
ing and HFT alike. The Deutsche Börse
(2011) has come to the conclusion that
regulatory intervention in HFT must not
hurt the proven positive effect on mar-
ket quality HFT has to offer. In particu-
lar, the variety of HFT strategies should
be preserved, as systemic risk should be
prevented. To achieve these goals, HFT
firms themselves may have to implement
security mechanisms – just as exchange
operators as Deutsche Börse already have.

Whichever regulatory rules may be im-
plemented in the end, the regulators will
have to make sure that these rules apply
to every European market and to every
market participant in Europe to the very
same extent.

Michael Krogmann
Deutsche Börse AG

5 Paradigm Change Through Algorithmic Trading

5.1 Introduction

Algorithmic trading nowadays often ac-
counts for more than half of trade vol-
ume and order volume at large stock
exchanges. Its net effects are generally
found positive by researchers. Only few
voices from the scientific community –
more, however, from traders – point out
negative effects of algorithmic trading. A
notable difference lies between empirical
findings – that usually find positive ef-
fects – on the one hand, and some theo-
retical works and especially the sentiment
of traders, who often express their frus-
tration about their computerized coun-
terparts, on the other hand.

5.2 Availability of Data

Most scientific studies about algorithm-
ic trading share one fundamental prob-
lem: data about algorithmic trading are
scarce. As one of the few stock ex-
changes, Deutsche Börse had for some
time quite reliable data on algorithm-
ic trading. Their "Automated Trading
Program" (ATP), which was in effect
from 2007 to early 2009, enabled them

to distinguish between algorithmic or-
ders and human ones (Deutsche Börse
2009). Hendershott and Riordan (2011),
Gsell (2009), Groth (2009), and Maurer
and Schäfer (2011) analyze such datasets
which contain flags for orders placed
within the ATP environment. Their re-
search questions differ, but they all more
or less conclude that the overall effect of
algorithmic trading is positive.

A fundamental critique of such analy-
ses is that algorithms usually work well
in "normal" markets and then show the
often-found positive effects. The models
that algorithms base on are abstractions
of reality and must fail to reflect it in its
entirety. If a market situation is not part
of the possibility space of the model, sev-
eral options are possible: The algorithm
halts trading and waits until the market is
"normal" again, thereby facing the risk to
generate possibly considerable losses. An-
other option is to continue trading using
the usual model, thus failing to trade op-
timally and possibly worsening the situa-
tion. Since the flash crash on May 6, 2010,
there have been repeated miniature flash
crashes that did not affect the whole mar-
ket but only individual stocks. For both
phenomena, algorithms are blamed to be
the cause of the market irregularities.

However, an effective approach to reg-
ulation should base on well-established
results. A lot of work has to be done
here. Above all, the insufficient availabil-
ity of appropriate data confines scien-
tific progress. The deduction of the ef-
fect of algorithmic trading on the mar-
ket from anonymous order book data can
only be very rudimentary. In our current
work, we attempt to find a way to an-
alyze algorithmic trading activity whilst
only using anonymous order book data
(Breuer and Burghof 2011). A manda-
tory flagging of algorithmic orders would
be desirable. Only then would it be pos-
sible to independently analyze algorithm-
ic trading from many points of view
and estimate the effect on the market.
The restrictive handling of historic ATP
data by Deutsche Börse does not build
confidence but could increase the prob-
ability that the sentiment towards AT is
influenced by irrational fears.

5.3 Information Efficiency

Recent studies (Hendershott and Riordan
2011; Gsell 2009; Groth 2009; Maurer
and Schäfer 2011) analyze rather short-
term aspects of market microstructure in
an AT environment. Indeed, its existence

745 alters behavioral incentives of other mar-
746 ket participants fundamentally and in the
747 long run. It is apparent that algorithms
748 process new information ever faster and
749 – assuming normal market conditions –
750 probably calculate its price impact better
751 than humans. It is still to be seen, how-
752 ever, how accurate trading algorithms
753 process information without slow human
754 traders monitoring them. Sometimes, the
755 superfast processing of news can be un-
756 desirable. An example for this is the news
757 about the bankruptcy of United Airways.
758 The airline’s stock price plummeted un-
759 til it became clear that the news was al-
760 ready a couple months old. Because the
761 possibility to extract yields from new in-
762 formation has a very short and decreas-
763 ing half-life, systems tend to react hastily
764 and without challenging the information.
765 Especially in delicate market situations,
766 rumors can develop a destructive power.

767 The effect that is likely to be most
768 important has however escaped scienti-
769 fic analysis so far. Capital markets are a
770 highly efficient instrument of capital al-
771 location, especially because a large num-
772 ber of actors feed information into the
773 price via their trading activity. This in-
774 formation comes from various sources;
775 it may be obtained haphazardly or with
776 some effort. Algorithmic trading uncov-
777 ers trade activity which is caused by that
778 information and uses this knowledge to
779 pocket a considerable part of the infor-
780 mation yield. The better these algorithms
781 work, the less money the informed per-
782 son will make out of this information. In
783 the long run, this could mean that the
784 costly generation of information turns
785 unprofitable, and in an extreme case even
786 the trade based on incidentally obtained
787 information does not pay anymore.

788 In such a hypothetical market, ever less
789 information is traded ever more perfectly
790 and faster. The market draws nearer and
791 nearer the weak form of market efficiency
792 (Fama 1970) or eventually even the semi-
793 strong form of market efficiency. At the
794 same time, it moves away from the strong
795 form of market efficiency, because the in-
796 centive to feed information into the mar-
797 ket becomes considerably less powerful.
798 It is this very effect that traders witness
799 when they trade against algorithms. They
800 know that information-based strategies
801 are detected rapidly and thwarted by ap-
802 propriate front-running strategies (Biais
803 et al. 2010; Cvitanic and Kirilenko 2010).
804 Surly, there is still a need for theoretical
805 as well as empirical analysis here, because
806 due to these thoughts, the usefulness of
algorithmic trading is subject to scrutiny.

5.4 Regulation and Regulatory Instruments

Regulatory considerations have to distin-
guish between the different types of algo-
rithms. Limit orders which are bogus or-
ders or part of quote-stuffing techniques
have to be considered under the light of
laws against market manipulation (e.g.,
§20a (1) No. 2 of the German Securities
Trading Act [WpHG]). Other strategies
improve the price quality by arbitraging
prices and equalizing them across differ-
ent trading venues. Because of the mar-
ket power of algorithms, there is the risk
that overly mechanic thinking and potent
algorithms may perturb the price forma-
tion process. Naturally it would be de-
sirable to capture the positive effects of
algorithmic trading and to dampen the
potentially negative ones. There may be
more than one way to reach this aim.

A simple ban of algorithmic trading, as
sometimes demanded by certain politi-
cal circles, cannot serve to reach this dif-
ficult aim. This would mean to also de-
stroy many preferable effects of algori-
thmic trading. Of course, a distinction of
algorithmic and “normal” trading is not
easy. And certainly market participants
would program algorithms that operate
in the gray area to hide their true nature.

Currently, regulatory bodies are dis-
cussing possible means (Dombert 2011).
The often contemplated lower boundary
for limit order lifetimes is regarded scep-
tically. The comprehensible reason is that
an efficient risk management of orders
would be drastically complicated – es-
pecially, but not exclusively, in volatile
markets. Dombert (2011) proposes an al-
ternative that is worth discussing. With
an order-transaction-ratio, the number of
orders divided by the number of trans-
actions would have to remain above some
exogenous constant.

In our view, a European regulatory
framework is desirable that defines the
playground for all market participants.
Within this framework, it should be left
to the trading venues how they wish to
treat algorithmic trading in the context
of their business model. Then it would
be up to them if they wanted to attract
algorithmic trading or to limit it in spe-
cific market conditions. Such a “menu-
approach” leaves it in essence to the in-
dividual trader if he or she wishes to
face the competition from algorithms
with all their positive and negative ef-
fects or evade them by trading on trading
venues with appropriate restrictions that

807 apply always or under specific market
808 conditions.

5.5 Conclusion

809
810
811
812 As long as algorithms operate in the
813 dark, there is a profound uncertainty
814 about the effect of their activities. There-
815 fore, algorithmic trading is partly in con-
816 tradiction to fundamental principles of
817 stock exchanges: bringing buyers and
818 sellers together in a transparent manner.
819 On stock exchanges, trust is paramount.
820 The opacity of algorithmic trading –
821 as comprehensible it may be from the
822 point of view of their operators – un-
823 dermines this principle. Currently, there
824 is no level playing field. However, it
825 is equally important to enable techni-
826 cal progress, which algorithmic trading
827 with its high-quality information pro-
828 cessing definitely is. An improved avail-
829 ability of data and associated scientific
830 research can help to develop reasonable
831 regulatory frameworks for algorithmic
832 trading. With the increasing importance
833 of this way of trading in mind, there is
834 less and less reason to doubt that the im-
835 plementation of appropriate regulatory
836 frameworks should have a high priority.

6 High Frequency Trading – A Central Bank View

841
842
843
844
845
846 The capital markets are currently at an
847 important juncture in their development.
848 Roughly half of all stock and foreign ex-
849 change trades conducted on the major
850 exchanges are no longer initiated by hu-
851 man traders; instead, they are the prod-
852 uct of computer algorithms that are able
853 to analyze large volumes of data and ini-
854 tiate hundreds of orders in fractions of
855 a second. Humans are increasingly being
856 eliminated from the immediate decision-
857 making process relating to the sale and
858 purchase of assets and being replaced by
859 software programs.

860 The speed with which orders are exe-
861 cuted has become to be the most impor-
862 tant factor and is now measured in milli-
863 and microseconds. New practices such as
864 “co-location” or “quote stuffing” – plac-
865 ing huge quantities of buy or sell orders
866 which the instigator intends to cancel al-
867 most immediately before they are exe-
868 cuted – have become important instru-

869 ments in the battle for the most rapid order
870 execution. Fundamental data on the
871 value of the respective securities or currencies
872 are of no, or only subordinate, importance
873 for HFT algorithms.

874 In HFT, positions are usually held for
875 between a number of milliseconds and
876 several hours. In today's high-speed markets,
877 the scales are no longer tipped in favor
878 of the investor who is best able to assess
879 the true value of an asset, but of the investor
880 able to trade fastest. True investments are
881 becoming increasingly rare.
882

883 Since the “flash crash” of May 6, 2010
884 (a roughly 15-minute phase of unusual and
885 irrational volatility on the New York Stock
886 Exchange), HFT has been called to the
887 attention not only of the general public
888 but also of regulators and central banks.
889

890 Numerous observers regard HFT as a
891 new technical means of executing existing
892 trading strategy rather than a strategy
893 in its own right. Advantages in terms
894 of speed have, they say, always been an
895 essential component of many successful
896 trading strategies. Seen from this perspective,
897 HFT is not a completely new phenomenon,
898 but rather a technical evolution of the securities
899 markets. HFT should be regarded merely as an
900 overarching term covering a multitude of
901 different fields of use. Among the many
902 tactics, several of the most important are
903 based on providing liquidity in stock market
904 trading (market making). Others can be
905 included under the category “statistical
906 arbitrage” and use algorithms to swiftly
907 identify and exploit profitable trading
908 opportunities based on price data. Others
909 belong to a category known as liquidity
910 detection, in which traders try to seek out
911 hidden large orders in order books. Many
912 critics term this “predatory trading”, and it
913 is suspected of being unfair and potentially
914 damaging to the market.
915

916 Against this complex background, any
917 assessment of HFT and all discussion
918 relating to potential regulation should,
919 where possible, be limited to the underlying
920 HFT strategy. From a central bank
921 perspective, a sweeping judgment on HFT
922 is therefore neither appropriate, nor would
923 it serve to improve the regulatory
924 framework for transparency, stability and
925 efficiency. That means that both the
926 advantages and disadvantages of HFT
927 need to be evaluated very specifically.
928 Statements that HFT is in general
929
930

either good or bad for the market should
therefore be viewed with caution.

HFT players and exchange operators
are at pains to stress that overall HFT
perceptibly improves market liquidity
and the efficiency of price discovery
(McEachern Gibbs 2009). The majority
of investors benefit from reduced bid/ask
spreads – a common measure of liquidity,
they say. This statement is backed up
by several scientific studies (Gomber
et al. 2011). However, there is increasing
evidence to suggest that, especially in
very volatile market situations, HFT
could prove problematic and could
additionally destabilize the market
(Broggaard 2010). This must be investigated
and, if found to be true, regulators must
step in to limit the risks for the financial
system.

The flash crash demonstrated that the
liquidity generated by HFT market makers,
which usually keeps transaction costs low,
may suddenly evaporate in difficult market
phases (NANEX 2010). Unlike regular
“human” market makers, who are obliged
to remain in the market even in times of
extremely volatile prices, HFT traders
are generally not bound by such constraints.
In good times, HFT traders therefore crowd
out normal market makers and often even
perform their role better, to the advantage
of all market players. In difficult markets,
however, there is a risk that trading flows
could collapse with all the attendant
problems for the market as a whole, as
HFT players withdraw. To many market
participants, the narrower bid/ask
spreads and higher trading volume
generated by HFT therefore only represent
“sham liquidity”. For this reason there
have been calls from various quarters
to oblige HFT market makers to remain
in the market even in times of high
volatility, similar to the obligations
imposed on normal market makers
(EC 2010). In other words, they should
start to take some responsibility for the
markets which they have, to date, merely
used to their advantage from their
superior position.

From a regulatory perspective, HFT
has proven problematic not only in these
rare but dramatic high volatility events,
but also in daily trading activities. While
bid/ask spreads have dropped significantly
in recent years thanks to HFT market
makers, the average period for which
such players hold positions has dropped
sharply. According to a study on the
flash crash, most HFT market makers
close out their positions after no more
than roughly 10 seconds (Kirilenko et

931 al. 2011). That means that the stabilizing
932 effect in the event of heightened market
933 volatility exerted by “normal” market
934 makers has given way to a “hot potato
935 effect”, where falling shares are merely
936 passed around at lightning speed.
937

As HFT has become more widespread,
938 the number of buy and sell orders has
939 increased dramatically in recent years.
940 The tactic known as quote stuffing, which
941 is used by several HFT algorithms, is
942 particularly problematic. For reasons of
943 trading strategy, the HF trader places a
944 large number of orders per second, only
945 to cancel them again almost immediately
946 before execution. The very high
947 cancellation rate this causes leads to a
948 marked divergence between apparent
949 market liquidity and actual trading
950 volume. An investor placing an order
951 in response to a bid or ask is therefore
952 often unable to carry out the transaction
953 at the limit shown. Although the explicit
954 transaction costs appear low, the implied
955 costs may be much higher. Apparent
956 market liquidity and the size of bid/ask
957 spreads are therefore not by themselves
958 reliable indicators of market liquidity
959 and efficiency.
960

An analysis of 1,172 trading days on
961 the New York Stock Exchange from 2007-
962 01-01 to 2011-09-14 that was carried out
963 recently by the research firm NANEX
964 showed that there were just 35 billion
965 real transactions for 535 billion quotes.
966 The quotes-to-trades ratio needed to
967 generate US\$ 10,000 in real transaction
968 volume moved from roughly 6–7 at the
969 beginning of 2007 to 60–80 in mid-2011.
970 Higher figures indicate a less efficient
971 market: more information is required to
972 achieve the same trading volume. Sudden
973 and dramatic spikes in the number of
974 quotes are increasingly being observed
975 for individual US stocks, with individual
976 HFT algorithms generating several
977 tens of thousands of quotes per second
978 for several seconds. Such bursts of
979 activity are frequently accompanied by
980 what are known as “mini flash crashes”,
981 where securities lose 20%, 40% or even
982 more than 50% of their value in a space
983 of seconds for no fundamental reason,
984 only to recover shortly afterwards. For
985 instance, according to the SEC, the
986 United States has witnessed more than
987 100 such inexplicable crashes since
988 mid-2010 which are suspected of being
989 caused by HFT algorithms.
990

Sending bids or asks is similar to
991 sending spam email: both are virtually
992 free for

993 the sender, but not for the recipient. For-
 994 warding and processing such large vol-
 995 umes of data causes a lot of problems
 996 and high costs for exchanges and mar-
 997 ket participants. Systems are often over-
 998 loaded, which is seen by many observers
 999 as one of the causes of the flash crash. To
 1000 make matters worse, certain HFT algo-
 1001 rithms send some of these quotes only to
 1002 cause other traders or algorithms to act in
 1003 a certain way, which they can, in turn, ex-
 1004 ploit. As a consequence, an ever increas-
 1005 ing number of institutional investors are
 1006 transferring their transactions away from
 1007 normal exchanges to “dark pools”, where
 1008 it is usually more difficult to make a profit
 1009 in HFT.

1010 The above-described criticisms intend
 1011 to show that HFT is a controversial issue,
 1012 requiring an exact analysis of the
 1013 details. In addition to “market friendly”
 1014 strategies that regulators regard as posi-
 1015 tive for the market – for instance, statisti-
 1016 cal arbitrage – there are also “unfriendly”
 1017 strategies that are seen as worrying. Oth-
 1018 ers are basically welcome but when actu-
 1019 ally applied on the market entail prob-
 1020 lems and dangers which should be elim-
 1021 inated. HFT market making is just such
 1022 an example.

1023 When considering the ultimate ques-
 1024 tion of whether there is a correlation
 1025 between HFT and market efficiency, it
 1026 should be borne in mind that market ef-
 1027 ficiency mainly means that the price of
 1028 an asset adjusts to fundamental changes
 1029 in its value rapidly. It is not immediately
 1030 clear how HFT algorithms can contribute
 1031 to that, as decisions are based only on
 1032 the status of the order book in the last
 1033 few seconds or indicators based on tech-
 1034 nical analysis. A block trade of 10,000
 1035 shares between two well-informed large
 1036 investors represents true price discovery
 1037 on the market. By contrast, shifting 100
 1038 shares back and forth between two HFT
 1039 algorithms in innumerable times makes
 1040 no equivalent contribution to trading ef-
 1041 ficiency, even if this takes place at im-
 1042 pressive speed. A market that is mainly
 1043 dominated by HFT is also a market where
 1044 most orders have lost all connection to
 1045 fundamental factors. And this correlation
 1046 between price and fundamental value is
 1047 what should, in the main, determine the
 1048 quality of a market.
